# Fast MapReduce over Apache HBase or How to Stop Worrying and Run MapReduce Directly Against Your HFiles

#### Keith Wyss

Software Engineer, Explorys Inc.

September, 24 2012

# Agenda

Introduction/Motivation

② Design

Operation

• Hadoop's stock key value store.

• HBase is columnar, and fairly heterogenous. Why?

- HBase is columnar, and fairly heterogenous. Why?
- A mix of memory and disk: Storefiles, a MemStore and a Block Cache.

- HBase is columnar, and fairly heterogenous. Why?
- A mix of memory and disk: Storefiles, a MemStore and a Block Cache.
- Because of low-latency writes, files are not typed by column.

- HBase is columnar, and fairly heterogenous. Why?
- A mix of memory and disk: Storefiles, a MemStore and a Block Cache.
- Because of low-latency writes, files are not typed by column.
- HBase is "garbage collected" and online-transformative.

 HBase provides a database that may be used a source for data processing via MapReduce. HBase makes it easy to perform batch processing at scale upon data that processes writes in real time. Most attractive feature to some.

- HBase provides a database that may be used a source for data processing via MapReduce. HBase makes it easy to perform batch processing at scale upon data that processes writes in real time. Most attractive feature to some.
- HBase interoperates with the rest of the Apache distributed stack. It utilizes zookeeper efficiently to spread the load of database operations evenly across a cluster if you structure the data properly.

- stack. It utilizes zookeeper efficiently to spread the load of database operations evenly across a cluster if you structure the data properly.

HBase interoperates with the rest of the Apache distributed

- HBase allows you to control your own destiny.
- Interface is always bytes.
- Lots of control. No mandatory schemas or serialization of data types.

 Running MapReduce over an HBase table using the TableInputFormat is slow. It is many times slower than processing the same data sourced from raw HDFS files.

- Running MapReduce over an HBase table using the TableInputFormat is slow. It is many times slower than processing the same data sourced from raw HDFS files.
- Three interfering use cases: read, write, and batch.

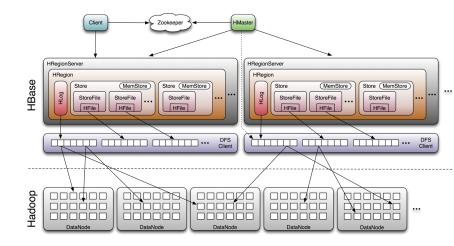

- Running MapReduce over an HBase table using the TableInputFormat is slow. It is many times slower than processing the same data sourced from raw HDFS files.
- Three interfering use cases: read, write, and batch.
- Running MapReduce over an HBase table will destroy your read performance. The scanners that the MapReduce job employs flood the block cache with data that does not reflect your random read access patterns. Also, be prepared to deal with thrashing as your HBase table is probably quite large and none of it will be read twice, so none of this cache management is beneficial.

- Running MapReduce over an HBase table using the TableInputFormat is slow. It is many times slower than processing the same data sourced from raw HDFS files.
- Three interfering use cases: read, write, and batch.
- Running MapReduce over an HBase table will destroy your read performance. The scanners that the MapReduce job employs flood the block cache with data that does not reflect your random read access patterns unless you explicitly turn them off. Also, be prepared to deal with thrashing as your HBase table is probably quite large and none of it will be read twice, so none of this cache management is beneficial.
- What is happening with a typical Scan?

# Architecture of an HBase Scan [4]

 Can we break the problems with running MapReduce over HBase down to a common root.

- Can we break the problems with running MapReduce over HBase down to a common root.
- The batch processing data access pattern is conflated with a typical client read scenario. MapReduce (TableInputFormat) data access is naive.

- Can we break the problems with running MapReduce over HBase down to a common root.
- The batch processing data access pattern is conflated with a typical client read scenario. MapReduce (TableInputFormat) data access is naive.
- Not naive as in dumb. Naive because of code re-use.

- Can we break the problems with running MapReduce over HBase down to a common root.
- The batch processing data access pattern is conflated with a typical client read scenario. MapReduce (TableInputFormat) data access is naive.
- Not naive as in dumb. Naive because of code re-use.
- Each map task uses the client API to scan over the Results in the HBase table. The primary advantage over typical use is merely concurrent scans allowing parallelism. The overhead of the client server architecture is offset by a large amount of buffering to reduce the impact of Remote Procedure calls, but it is far from the mark of a direct file-system access even if the data is local to the MapReduce task.

#### Direct Access

• What do we want instead?

#### Direct Access

- What do we want instead?
- An InputFormat that allows direct, read-only subscription to the StoreFiles for an HBase Table.

#### Direct Access

- What do we want instead?
- An InputFormat that allows direct, read-only subscription to the StoreFiles for an HBase Table.
- Through some conversation with the HBase committers, especially St. Ack, we were told
  - We were crazy for thinking of this.
  - More direct data access is something that's been requested before.
  - We might have a viable approach by spinning up our own Region objects and using those to gain access to the underlying HFiles.
- There are a few contraindications to the approach that we will discuss later.

 Each storeFile is a column-family specific sorted list of KeyValues. The storefiles themselves are ordered by the timestamps.

- Each storeFile is a column-family specific sorted list of KeyValues. The storefiles themselves are ordered by the timestamps.
- The approach is to treat each HFile as a heap of KeyValues.
  We then built an outer heap of HFiles where the comparator is the KeyValue.COMPARATOR applied to the top element of the heap.

- Each storeFile is a column-family specific sorted list of KeyValues. The storefiles themselves are ordered by the timestamps.
- The approach is to treat each HFile as a heap of KeyValues.
  We then built an outer heap of HFiles where the comparator is the KeyValue.COMPARATOR applied to the top element of the heap.
- Then we merge the results into a Result object as they are read in to provide the familiar pair of rowkey and Result object.

- The approach is to treat each HFile as a heap of KeyValues.
  We then built an outer heap of HFiles where the comparator is the KeyValue.COMPARATOR applied to the top element of the heap.
- Then we merge the results into a Result object as they are read in to provide the familiar pair of rowkey and Result object.
- Back to online-transformation again. Tombstone markers handle with reverse-timestamp sorting.

# Anatomy of an HFile [1, 2]

A Typical HFile		
1	Data Block 0	
2	Data Block 1	
3	Meta Block	
4	File Info	
5	Data Block Index	
6	Meta Block Index	
7	Trailer	

A Typical DataBlock

## **Implementation**

- Here at Explorys, we implemented this proposed InputFormat to be used as a plug and play replacement for TableInputFormat.
- Almost...
- The code is hosted on github at https://github.com/ExplorysMedical/Apothecary
- Problems? Compaction and Region Splitting. Memstore access. Why?

# Dealing with HBase Data Administration

- Turn off data source or funnel into temporary storage.
- ② Trigger flush and compaction.
- Wait for flush and compaction to finish. All the data is on disk.
- Oreate a log of the existing storefiles.
- Run the MapReduce Job
- Check the log to see that the state of the table didn't change (region splits or compaction).
- Possible do-over.

# Dealing with HBase Data Administration

- Turn off data source or funnel into temporary storage.
- 2 Trigger flush and compaction.
- Wait for flush and compaction to finish. All the data is on disk.
- Oreate a log of the existing storefiles.
- Run the MapReduce Job
- Oheck the log to see that the state of the table didn't change (region splits or compaction).
- Possible do-over.
- That's a lot. What can we skip?

- Turn off data source or funnel into temporary storage.
- 2 Trigger flush and compaction.
- Wait for flush and compaction to finish. All the data is on disk.
- Oreate a log of the existing storefiles.
- Run the MapReduce Job
- Check the log to see that the state of the table didn't change (region splits or compaction).
- Possible do-over.
- That's a lot. What can we skip?
- Hard links?

	TableInputFormat	HFiles
Copying a Table	5:06	0:26
Explorys Indexing Job	1:50	0:30

	TableInputFormat	HFiles
Copying a Table	5:06	0:26
Explorys Indexing Job	1:50	0:30

- Indexing Job run with 800 input splits, about 300 concurrent mappers.
- Copy Job run with 800 input splits, 95 concurrent Mappers.
- Significantly less cluster resources allocated to HBase on Copy Job.

	TableInputFormat	HFiles
Copying a Table	5:06	0:26
Explorys Indexing Job	1:50	0:30

- Better over large tables where cache doesn't have an impact.
- Worth the operation overhead in some circumstances.
- Major motivation for hard links and/or table snapshotting.

	TableInputFormat	HFiles
Copying a Table	5:06	0:26
Explorys Indexing Job	1:50	0:30

• Due to a bug scanner caching for the control group was accidentally turned off.

	TableInputFormat	HFiles
Copying a Table	0:33	0:26

- Still might be beneficial if tables are constructed using bulk generation.
- RPC calls were not as big of a deal as initially thought.

#### **Problems**

- Serious memory usage. HFile block indexes can be quite large, although needn't be loaded in full since HBase 0.92 [3]
- Operational constraints unwieldy. HBase Administration is asynchronous, doesn't return monitoring object.
- Tenuous relationship with non-exposed API. No guarantees that upgrades won't break it.
- Not tested with filesystems other than HDFS.
- Aside from compaction rearranging files, Memstore is not included. We could possibly read WAL and construct our own memstore if compaction problem is solved.
